

# Code Review

My program's purpose is to be an interactive game with your cat that outputs a wind generator using Pure Data and you can manually change the frequency of the wind before officially running the program. Using visual studio code, there's a plugin to run the index.html page which is the home page to open the project and everything should run as a whole.

Another step to run this project you have to do everything within the folder itself. The only thing you have to change and edit within the code manually is the final destination of catMusic.pd because it's a hardcoded file location as /ACI/catMusic.pd.

There's a simple button to start the application which will take you to another page and have another two buttons one of them leads back to the page and the other starts the pure data information which is using webPD to translate the pure data code into a javascript file.
